ABSTRACT OF THE DISCLOSURE

There is provided a service processor which can easily take an adequate measure for an occurrence of a fault. Each service processor decides whether a setting of storing is described or not in individual instruction information. When the setting of storing is not performed, processing of the service processor is terminated here. When the setting of storing is performed, source data of a process object document is stored in relation to a service ID to identify a service requested from a cooperation process server. Moreover, each service processor decides whether current time is a predetermined timing (for example, predetermined time or time instructed by a user or the like) or not. When the current time is the predetermined timing, the source data stored in relation to the service ID is transferred to the cooperation process server.
